Psychology 4165, Spring 2008  
Laboratory 4  
Group Project

**This Page (except for this line) Intentionally Blank**

## Introduction

With this laboratory you will learn how to go through the various stages of scientific experimentation: from getting ideas for research to completing a finished experiment. You will work in groups to brainstorm about what questions to ask, then to search the recent experimental literature, then to design an appropriate experiment and finally to carry out the experiment and write up the results. You will proceed in six steps:

1. The class will be divided into four or five groups. Each group should choose a group leader to keep track of the group discussion by taking notes and then to summarize it to the rest of the class.
2. Each group will then discuss for 10 minutes what questions about perception they would want to answer. The group should make a list of the three most interesting questions.
3. Each group leader will make a three minute (maximum) presentation of their group's questions. We will keep track of these ideas by writing them down on the blackboard. At the end of the presentations there will be at least 10 questions. There will then be a class discussion about these ideas. Each person should write down the three questions that most interest him/her.
4. The groups will now reconvene and pick one question from the lists of questions compiled by the group members. Each group member should go to the library and locate two papers published within the last ten years related to the question. The papers should be published in one of the journals listed below. Each group member should make copies of these articles for themselves and for of the other group members.
5. The group members should read all the articles gathered by their group and discuss these papers among themselves. The purpose of these discussions is to identify a question that can be answered by a relatively simple experiment.
6. The group should now design an experiment that will answer the question your group has chosen. It will be very helpful during this stage to refer to the relevant chapters of the book *Doing Psychology Experiments* (Martin, 2007). Before the experiment is carried out you need to have it approved by the instructor or the TA.

## Laboratory Report

The first draft of your lab report should contain **four** of the standard six parts: **Cover Sheet, Introduction, Methods, Results, Discussion and References**. In the introduction explain what the question is that you propose to answer. You should refer to the relevant literature, including the papers that your group has assembled. The introduction typically starts out broadly and concludes with the specific question you intend to answer. In the methods section describe what you propose to do. Make this section as concrete as possible at this stage. Include a description of the equipment you need and the specific procedure you will follow. Be explicit

about what independent variable(s) you will manipulate and what values they will have. Be explicit about the dependent variable(s) you will collect and how you will analyze the data. Include a reference list of all the papers you have cited. Use the standard format of the American Psychological Association for citations and references.

Conciseness and clarity are extremely important characteristics of good scientific writing. Strive for them. We will give you feedback on your first draft before you actually start to carry out your experiment. Remember: keep these reports short, clean, and clear. **First draft is due in lab on 9 or 11 October 2007**

### Suggested Journals

*Journal of Experimental Psychology: Human Perception and Performance*  
*Perception and Psychophysics*  
*Vision Research*  
*Perception*

### Schedule

1. **26 and 28 February 2008**  
First draft of proposal due (Cover Page, Introduction, Methods, Anticipated Results and Analyses, References)
2. **4 and 6 March 2008**  
Work on group projects
3. **11 and 13 March 2008**  
Second draft of group proposal due
4. **18 and 20 March 2008**  
Data Collection
5. **1 and 3 April 2008**  
Data Collection
6. **8 and 10 April 2008**  
Data analysis
7. **15 and 17 April 2008**  
Work on research presentations  
Turn in PowerPoint file of poster.
8. **21 April 2008 (Monday) Undergraduate Research Day, 15:00–17:00, UMC**  
**24 April 2008 (Thursday)** Oral presentations of All Group Projects: Both Laboratory Sections (20 points)
9. **29 April 2008 (Tuesday)**  
Final version of report due. Each group turns in one paper with a Cover page, Introduction, Methods, Results and Reference section. Each member of the group turns in their own

discussion section (80 points total: 40 points for group report, 20 points for individual discussion and 20 points for the group presentation).

### Hints for Making Posters

Posters are more formal than verbal presentations, but you still don't want to have too much material that will clutter the poster and distract the reader from understanding the main points you want to make. It is easy to prepare your posters using PowerPoint. Start up PowerPoint and make a new slide show with a single slide. You will make your poster on this single slide. Go to the File menu and select Page Setup... Choose Custom paper size and set it to 36 inches wide and 24 inches high. The dialog box should look like this:

Below is a sample poster: When making the layout keep the following points in mind:

- The font size of the title should be around 80 points and should fit on one line
- The font for the authors names and affiliation should be around 60 points
- About 1/3 of the area of the poster should be blank
- Use attention-grabbing graphics (a picture is worth a thousand words). The goal is to attract and focus attention on the important parts of your poster.
- Don't make your poster cluttered, put only essentials on it. You want to make it easy for the reader to grasp the main conclusion.

We will print the posters for you here in the department. So you should concentrate on getting the layout right. Here are two examples of posters from previous classes.

**Speech Perception: The Effect of Priming on the Perception of Sine Wave Synthesized Speech**  
 Estelle Carlton, Jim Laudin, Kristen Toll & Thu Yen Tran

Sponsored by: Lewis O. Harvey, Jr. & Benjamin L. Jacobson  
 PSYC 4165, Department of Psychology

The purpose of this experiment was to examine the effect of priming on the perception of sine wave synthesized speech. Sine Wave Synthesized (SWS) speech is a simplified version of the speech signal, reduced to only three sine waves. The first two sine waves of SWS speech (220 and 330 Hz) are the same as the first two sine waves of natural speech. The third sine wave (440 Hz) is the only one that is different. The purpose of this experiment was to examine the effect of priming on the perception of SWS speech. The use of a vowel as a prime was expected to have a greater effect on the perception of SWS speech than the use of a consonant as a prime. The use of a vowel as a prime was expected to have a greater effect on the perception of SWS speech than the use of a consonant as a prime.

The speech signal is a complex waveform, which is composed of many different frequencies. In order to synthesize speech, we need to know the frequencies of the different components of the speech signal. The first two frequencies of the speech signal are the same as the first two frequencies of natural speech. The third frequency of the speech signal is the only one that is different. The purpose of this experiment was to examine the effect of priming on the perception of SWS speech. The use of a vowel as a prime was expected to have a greater effect on the perception of SWS speech than the use of a consonant as a prime.

**Procedure**  
 The participants were not told to listen to any speech. They were told to listen to the speech signal and to respond to the speech signal. The speech signal was presented to the participants in a controlled environment. The participants were asked to respond to the speech signal in a controlled environment. The participants were asked to respond to the speech signal in a controlled environment. The participants were asked to respond to the speech signal in a controlled environment.

**Results**  
 Comparison of the responses was not conducted across the eight sentences. The mean comparison of the responses was not conducted across the eight sentences. The mean comparison of the responses was not conducted across the eight sentences. The mean comparison of the responses was not conducted across the eight sentences.

**Discussion**  
 The results of this experiment support the hypothesis that priming has a significant effect on the perception of SWS speech. The results of this experiment support the hypothesis that priming has a significant effect on the perception of SWS speech. The results of this experiment support the hypothesis that priming has a significant effect on the perception of SWS speech.

**Method**  
**Participants**  
 Twenty-eight students from the University of Colorado, Boulder enrolled in a psychology class participated in this experiment. The average age of the participants was 19.5 years old.

**Apparatus**  
 The speech signal was presented to the participants using a computer. The speech signal was presented to the participants using a computer. The speech signal was presented to the participants using a computer.

**Olfactory Memory and Cognitive Recall**  
 Caitlin Froehlich, Jessica Graham, Jessica LaBudda, Colleen Micalizzi and Jessica Munday  
 Psychology of Perception (PSYC 4165)  
 Sponsors: Lewis O. Harvey, Jr. and Benjamin L. Jacobson

Olfaction is not forgotten as quickly as other perceptual events and an ability to evoke olfactory memories that other sensory stimuli. Olfactory stimuli create a unique memory in the brain related to the scent which when paired with another sensory cue is stronger than when it is presented alone. Through this experiment, we predict that smell is recalled more often when paired with a cognitive task, specifically writing a word or drawing a picture associated with a smell. The basis for this hypothesis is olfactory memory occurs because humans have been found to assign verbal representations to the olfactory stimuli. 30 results were randomly chosen to be presented for the first training session in the three different experimental groups: visual imagery, word association, and control. The control training session consisted of 30 results randomly presented with the participants sitting on a scale of confidence that the smell has been previously experienced. The results showed that there was no significant difference between any of the groups, thus demonstrating that cognitive processes do not have an impact on olfactory recall.

**Method**  
**Participants**  
 The participants in this experiment were 31 college students at the University of Colorado, Boulder enrolled in a psychology class. None of the participants were paid for their time. The participants were both male and female and ranged in age from approximately 18 to 25. All participants were randomly assigned to one of the following groups: control, visual imagery, and word association.

**Apparatus**  
 120 plastic Ziploc bags containing various olfactory stimuli. A list of smells is located in Appendix 1. For the visual imagery and word association groups a pencil and paper was provided.

**Procedure**  
 30 smells were randomly chosen by the experimenter for the first part of the experiment. All three groups were blindfolded and the experimenter opened a plastic bag and instructed the participant to smell for five seconds. The order in which the smells are presented was random for each participant. Immediately following smelling the contents of the container, the control group waited for 15 seconds until the next smell was presented. Within a time span of 15 seconds, the word association group was instructed to write one to two words that best described the smell that was perceived. Also, within a time span of 15 seconds, the visual imagery group was instructed to draw a picture that they associated with that particular. The procedure was repeated for each group for all of the remaining smells. All groups were given a 15 minute break. Following the break, 40 smells were presented, 20 of which were from the original training phase, and 20 new smells. Using the six-point rating scale shown below, each participant rated each smell on his/her confidence that the smell had been previously experienced in this experiment (one of the training smells) (Harvey 3).

Zucco, G. (2002). Anomalies in Cognition: Olfactory Memory. *European Psychologist*, Vol. 8, No. 2, pp. 77-86.

**Results**  
 The results to this experiment show no significant difference between the participants ability to recall olfactory stimuli when paired with a word association or picture association. Though there were no significant values the participants in the word association group recalled more smells than that of the picture association group or control group.

**Conclusions**  
 Even though the results did not support our hypothesis the word association group did have a higher sensitivity than both the control group and the visual imagery group. Thus, if this experiment was conducted again with more accuracy it is likely that significance would be found to support the hypothesis that pairing olfactory memory with a cognitive cue aids in more efficient recall.
