## Using the R Statistical Computer Program

R is a powerful statistical computer program that is freely available under the General Public License (GPL). It runs under Unix and Linux, Microsoft Windows and Macintosh operating systems. Download your own copy here: <a href="http://www.r-project.org/">http://www.r-project.org/</a>. To get started, go here: <a href="http://www.statmethods.net/">http://www.statmethods.net/</a>. Below are R commands (in **bold**) used to solve some of the math skills questions that are on the syllabus. The hash marks (#) are comments to clarify what is going on.

```
# Question 3:
x <- c(10, 9, 12, 11, 8.5, 13, 8, 10, 7, 11.5)# create data vector
                                      # compute the mean of the numbers in x
# compute the standard deviation
mean(x)
sd(x)
# Ouestion 4:
obs <- c(174, 172, 104, 92, 41, 8) # observed data
prd <- c(175.5, 167.8, 106.5, 90.4, 44.3, 6.5)# predicted data
# Question 5:
# There are two ways to test the hypothesis: t-test or ANOVA
# They will give exactly the same results: t^2 = F
# Step 1: make a data frame with three columns
         Make the subject, levels, and dependent variable vectors and
         Now assemble the factors and data into a data frame
sj <- factor(c("S01","S02","S03","S04","S05","S06","S07","S08","S09","S10"))
iv <- factor(rep(1:2, each = 5))  # indep factor with 2 levels</pre>
dv \leftarrow c(8.0, 9.0, 7.5, 7.0, 8.5, 10.0, 9.5, 11.0, 9.0, 10.5)# dep var
df <- data.frame(sj, iv, dv)</pre>
# Step 2: compute a t-test for two independent groups
with(df, t.test(dv[iv == 1], dv[iv == 2], paired = FALSE))
# Step 3: compute and print the ANOVA comparing the two levels of
# the independent variable (iv)
summary(aov(dv \sim iv, data = df))
# Step 4: print summary table in nice format
xbar <- tapply(dv, iv, mean) # holds the means
sdev <- tapply(dv, iv, sd) # holds the standard deviations
numb <- tapply(dv, iv, length) # holds the number of samples
cbind(mean=xbar, std.dev=sdev, n=numb)
# Question 6:
# Questions 7 & 8:
# Questions / & 8:

x <- c(1.0, 3.0, 5.0, 7.0, 9.0)  # x data vector

y <- c(4.1, 9.9, 16.1, 22, 27.9)  # y data vector

df <- data.frame(x, y)  # put x and y vectors into a data frame

reg <- lm(y ~ x, data = df)  # compute the regression

summary(reg)  # prints summary of the regression

plot(df)  # plots graph of data

abline(reg)  # plots the regression line
```
